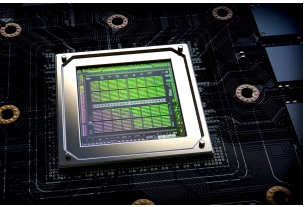
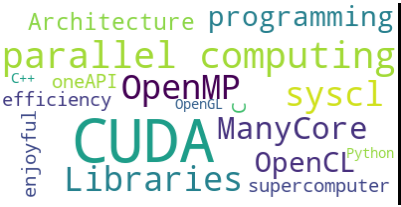
HPS

julian.kunkel@gwdg.de

Julian Kunkel

Welcome to the Practical Course on High-Performance Computing





Recording!

- This broadcast channel will be recorded via BBB
  - This includes your video, audio (if shared), and chat messages
  - We can start/stop video recording if necessary
- Recordings will be available 1-2 days later
- We **may publish** selected trainings on our YouTube channel
  - Will include video, audio if shared
  - Use the chat in broadcast in the case of questions
    It won't be rendered for the YouTube video

Outline

Learning Objectives of the Module

- Parallelize sequential code using MPI and OpenMP
- Justify performance expectations for code snippets
- Sketch a typical cluster system and the execution of an application
- Characterize the scalability of a parallel app based on its performance
- Analyze parallel app performance using performance analysis tools
- Describe the development and execution models of MPI and OpenMP
- Construct small parallel apps that demonstrate the features of parallel apps
- Demonstrate the application of software engineering concepts
- Demonstrate the usage of an HPC system to load existing software packages and execute parallel apps and workflows

Organization of the Module

- Attendees
  - GWDG academy users
    - Researchers, PhD students, users of HPC systems in the NHR and local
  - University students
    - Need to develop software after the course to obtain their credits
    - Details will be explained at the end of the week
- Webpage https://hps.vi4io.org/teaching/summer_term_2026/pchpc
  - Links to Slides, exercise sheets, and more
- Communication via two BBB channels
  - Broadcast: you should listen to this one the whole week
    - The trainer will present slides, walk through exercises, share suggestions
    - Do not share video, note that we record this channel
  - Breakout: room for group work and general support requests during sessions
- For university attendees: may use StudIP for asynchronous communication
  - We use it for announcements
  - Please use it for any purpose around the topic!

Organization of the Module

- Block course: 1 week of training (this week)
  - Mix of lecture, hands-on tutorials, and guided exercises
  - May contain introductory and harder tasks
  - You can take a break anytime as necessary (particularly during exercises)
- Group work and community (30 min)
  - Learning in a virtual environment is difficult, therefore, we form groups!
  - Imagine you sit in a room with 4 people to share ideas and work together
  - The group *should* stick together in a breakout room the whole week
  - We will **now** organize teams of 5 attendees
    1. Join the Breakout BBB session
    2. Room 1-4 are reserved for GWDG-Academy attendees
    3. Room 5 are for DLR attendees
    4. Room 6+ are for University attendees
    5. Join a random room with < 5 attendees - or with peers you know
    6. Work on the "Welcome" groupwork (next slide)

Group Work: Welcome

- Tasks:
  1. Introduce yourself to your peers
  2. Describe with one sentence why you joined this course
  3. Have one of you share the screen of the course
- Time: 25 min
- Organization: breakout groups - Please use your mic and chat

Support Structure

- Support request takes place primarily in the Breakout BBB
  - This channel will never be recorded
  - Ask questions to colleagues and to us
  - We will support your learning journey but **YOU** are responsible for it
- Utilize screen sharing (similarly as we would if in the same room)
- L1: Try to resolve issues in your breakout group with your peers
  - Please use your microphone, share screen and work together (on issues)
  - It is beneficial for learning
- L2: Ask questions in the global breakout chat
  - We have trainers that will reply to you, maybe other peers will reply too!
- L3: If breakout chat doesn't help, a trainer will connect your breakout group
- If we realize that the issue should be given to all, the trainer will use the broadcast channel to demonstrate how the issue can be resolved

A Typical Session

1. Trainer gives an introduction to the topic
   - May include some short/small group works (for your breakout group)
2. Trainer may give a tutorial to overcome introductory obstacles
   - Step-by-step walkthrough
   - We provide an exercise sheet describing the steps and giving an introduction
3. Attendees work on tasks individually and in their breakout group
   - We provide an exercise sheet
   - Attendees should store their results (e.g. in a Git repository)
4. End of the session, volunteers share results on the broadcast channel

Credits

- This course can be taken via the following modules
  - Modul M.Inf.1829: Praktikum High-Performance Computing (6C)
  - Modul B.Inf.1803: Fachpraktikum I (5C)
  - Modul B.Inf.1804: Fachpraktikum II (5C)
  - Modul B.Inf.1805: Fachpraktikum III (5C)
  - Modul B.Inf.1833: Fachpraktikum Data Science (9C)
  - Modul B.Inf.1834: Fachpraktikum Data Science I (klein) (5C)
  - Modul B.Inf.1835: Fachpraktikum Data Science II (klein) (5C)
- Of these, only M.Inf.1829 is graded
  - Can be extended via M.Inf.1834 for a total of 9C
  - Grading is also stricter, see final assignment sheet for details
- Make sure to register for the one you want

Learning Outcomes

After the session, a participant should be able to:

- Characterize distributed, parallel computing and HPC
- Describe how the scientific method relies on HPC
- Sketch generic parallel/distributed system architectures
- Sketch a simple program for vector addition using pseudocode

Outline

Scientific Method

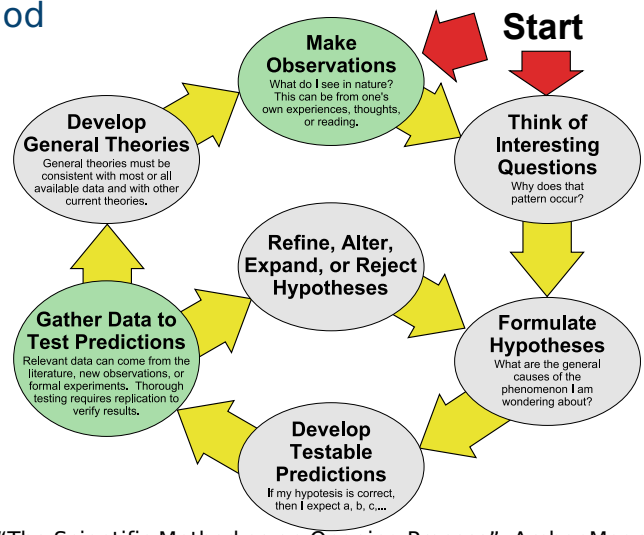


Figure: Based on “The Scientific Method as an Ongoing Process”, ArchonMagnus
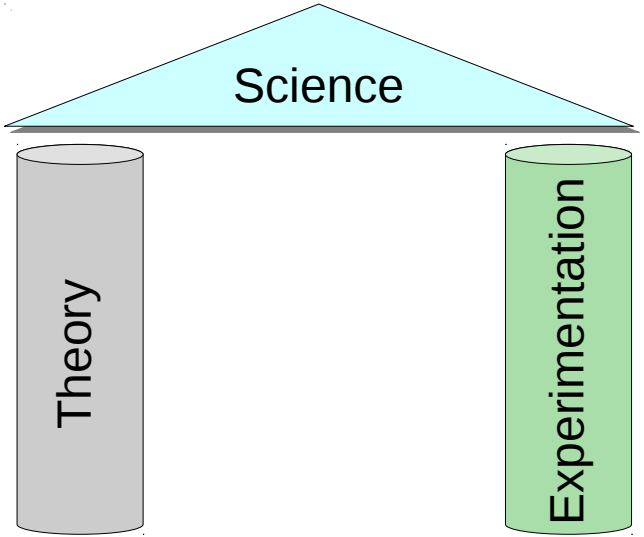
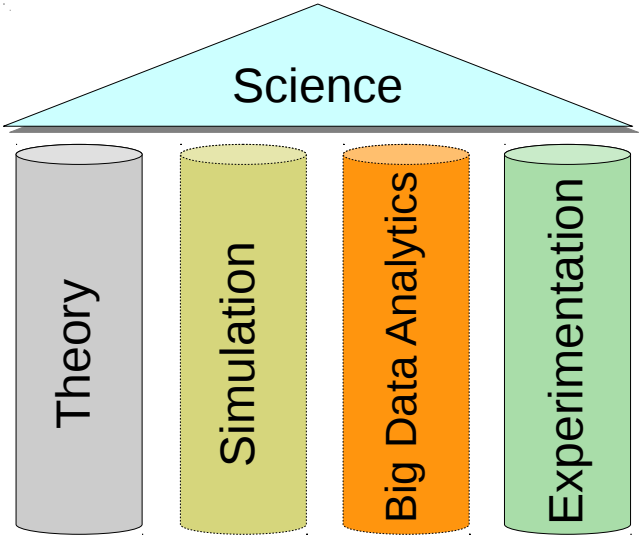
https://en.wikipedia.org/wiki/Scientific_method

Pillars of the Scientific Method



Pillars of Science: **Modern Perspective**



Computer-Aided Simulation

Modelling and Simulation of the world replaces traditional experiment

Computer simulation is an instrument empowering scientists with

- Arbitrary temporary and spatial resolutions
- Manipulation of arbitrary (model) parameters
- Reproducibility
- Conducting experiments that are infeasible due to ethics, risks, or costs
  - Impact of the explosion of nuclear power plant
  - Impact of poison to humans
  - Influence of brain neurons
- Prediction of the future
  - Weather forecast, climate
  - COVID19 infection progression ...

Simulation is Compute and Memory-Intense

Examples

- Simulation of billions of neurons requires certain memory
- The Modelling of plane engines consists of billions of "elements"
- AI-Models compute with 1000s of GPUs
- Deadline of simulations
  - Weather prediction demands high resolution and completion within 24 hours.

Simulation is Compute and Memory-Intense

Examples

- Simulation of billions of neurons requires certain memory
- The Modelling of plane engines consists of billions of "elements"
- AI-Models compute with 1000s of GPUs
- Deadline of simulations
  - Weather prediction demands high resolution and completion within 24 hours.

How can we cope with the huge demand for compute/storage resources?

- A single PC/server/workstation is not able to solve compute task

Simulation is Compute and Memory-Intense

Examples

- Simulation of billions of neurons requires certain memory
- The Modelling of plane engines consists of billions of "elements"
- AI-Models compute with 1000s of GPUs
- Deadline of simulations
  - Weather prediction demands high resolution and completion within 24 hours.

How can we cope with the huge demand for compute/storage resources?

- A single PC/server/workstation is not able to solve compute task
- We need more performance ... High performance ...

High-Performance Computation

Relation of the Scientific Method to Simulation

Simulation models real systems to gain new insight

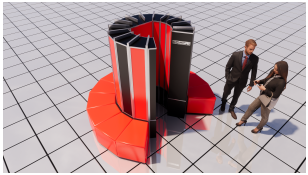
- Instrument to make observations, e.g., high-resolution and fast timescale
- Typically used to validate/refine theories, identify new phenomena
- Classical computational science: hard facts (based on models)
- The frontier of science needs massive computing resources
- Data-intensive sciences like climate impose challenges to data handling, too

Outline

High-Performance Computing

Definitions

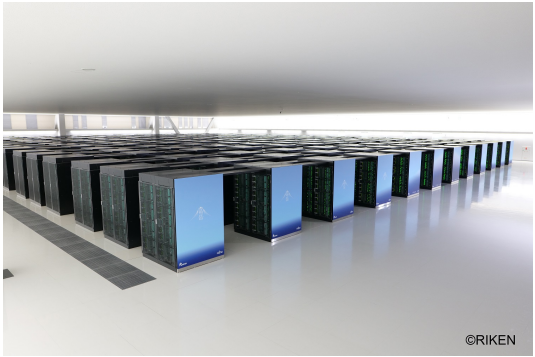
- HPC: Field providing massive compute resources for a computational task
  - Task needs too much memory or time for a normal computer
  - $\Rightarrow$ Enabler of complex challenging simulations
- Supercomputer: aggregates power of many compute devices
  - In the past large monolithic computers such as the Cray
  - Nowadays: 100-1,000s of servers that are clustered together
  - Comparison: Car is to Formula-1 like Computer to Supercomputer



Introducing: One of the Fastest Supercomputers of the World

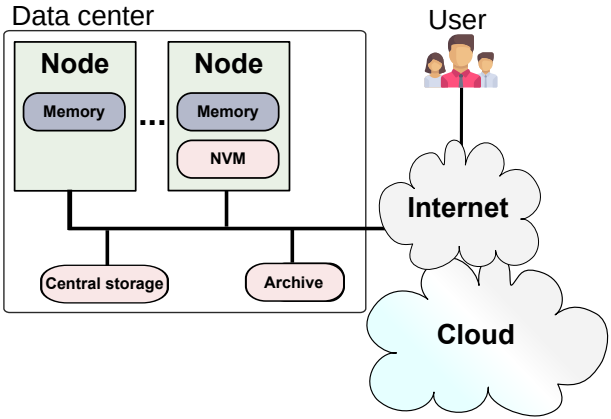
FUGAKU at RIKEN Center for Computational Science

- Nodes/Servers:
  - 158,978, 7.6 Million CPU Cores
- Compute Peak:
  - 540 Petaflop/s (10^{15})
- Memory: 5 Petabyte
- Storage: 150 Petabyte HDDs
- Energy Consumption: 30 Megawatt
- Costs: 1 Billion (program) $



The Top500 is a list of the most performant supercomputers

Supercomputers & Data Centers



Credits: STFC

JASMIN Cluster at RAL / STFC

Used for data analysis of the Centre for Environmental Data Analysis (CEDA)

HPC in Göttingen

GWDG: university data center and providing innovative technology solutions

- HPC systems for local scientists, German-wide and for DLR
- Integrates research for HPC systems and services

Outline

Distributed Computing

Field in computer science that studies **distributed systems**[1]

Definition

- System which components[2] are located on different networked computers
- Components communicate and coordinate actions by passing messages
- Components interact to achieve a common goal
- *Wider sense*: autonomous processes coordinated by passing messages

Characteristics

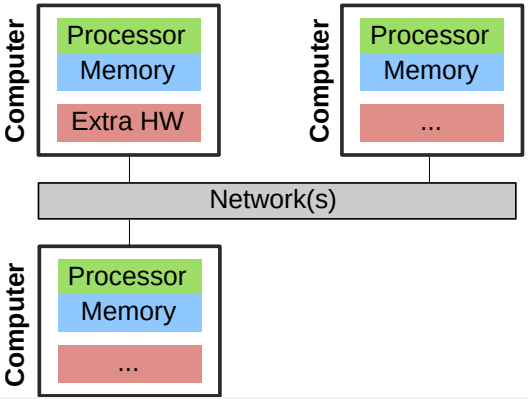
- Distributed memory: components have their own (private) memory
- Concurrency of components: different components compute at the same time
- Lack of a global clock: clocks may diverge
- Independent failure of components, e.g., due to power outage

[1] https://en.wikipedia.org/wiki/Distributed_computing

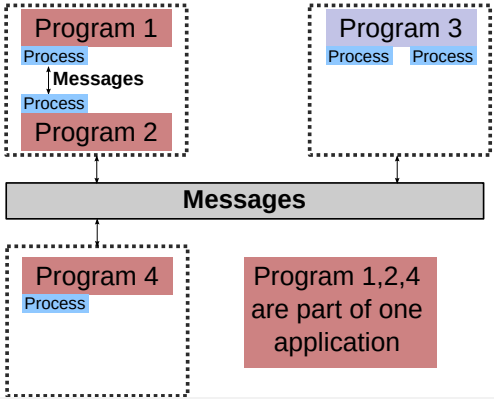
Example Distributed System and Distributed Program

- A **distributed program** (DP) runs on a distributed system
  - Processes are instances of one program running on one computer
- A **distributed application/algorithm** may involve various DPs/vendors

Hardware perspective



Software perspective (mapped to hw)



Example Distributed Applications and Algorithms

Applications

- The Internet and telecommunication networks
- Cloud computing
- Wireless sensor networks
- The Internet of Things (IoT) – “everything is connected to the Internet”

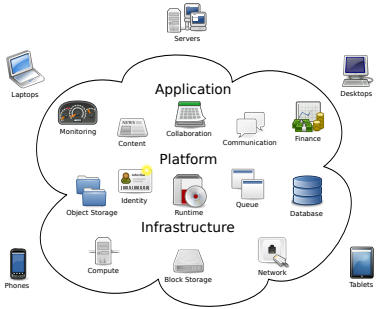
Algorithms (selection from real-world examples)

- Consensus: reliable agreement on a decision (malicious participants?)
- Leader election
- Reliable broadcast (of a message)
- Replication

Cloud Computing

Definition

- On-demand availability of computer system resources (data storage and computing)
  - Without direct active user management
- Relates to distributed resources
  - provided by data centers to users over the Internet
- Fog/Edge Computing: brings cloud close to user



Cloud computing

Examples

- Applications: Dropbox, Google Mail, Office 365
- Infrastructure: Amazon, Google, Microsoft, Oracle

Image source: Frank, B. Wilson - CloudNINE, https://en.wikipedia.org/wiki/Cloud_computing

Challenges using Distributed Systems

- Programming: concurrency introduces new types of programming mistakes
  - It is difficult to think about all cases of concurrency
  - Must coordinate between programs
  - No global view and debugging
- Resource sharing: system shares resources between all users
- Scalability: the system must be able to grow with the requirements
  - numbers of users/data volume/compute demand
  - retain performance level (response time)
  - requires to add hardware, though
- Fault handling: detect, mask, and recover from failures
  - Failures are inevitable and the normal mode of operation
- Heterogeneity: system consists of different hardware/software
- Transparency: Users do not care about how/where code/data is
- Security: Availability of services, confidentiality of data

Outline

Definition: Parallel Computing

Many calculations **or** the execution of processes are carried out simultaneously[3]

Characteristics

- Goal is to improve performance for an application
  - Either allowing to solve problems within a deadline or increased accuracy
- Application/System must coordinate independent parallel processing
  - There are various programming models for parallel applications
- Different architectures speed up computation: **may use** distributed systems

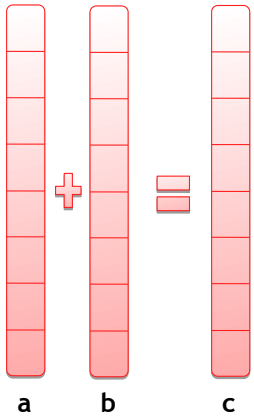
Levels of parallelism (from hardware perspective)

- Bit-level: process multiple bits concurrently (e.g., in an ALU)
- Instruction-level: process multiple instructions concurrently on a CPU
- Data: run the same computation on **different data**
- Task: run **different** computations concurrently

[3] https://en.wikipedia.org/wiki/Parallel_computing

Bit-Level Parallelism: Vector Parallelism with SIMD

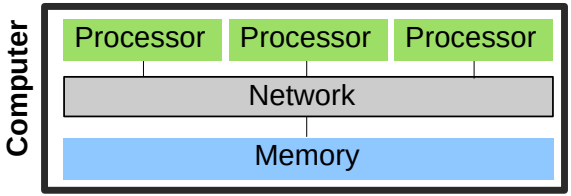
- SIMD = Single instruction multiple data
  - Apply the same operation on multiple data
- Example: Vector addition: a = b + c
  - $c_i = a_i + b_i$ for all vector elements i
- AVX-512 works on 8x 64-bit elements in parallel
  - i.e., run same operation on all
  - The example Xeon can do 8xFP64 FMA ($a = a + (b \cdot c)$) per cycle



Parallel Architectures

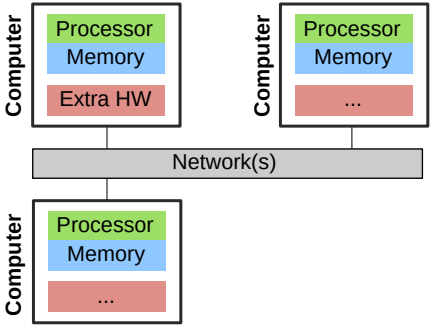
In practice, systems are a mix of two paradigms:

Shared memory



- Processors access joint memory
- Enabled communication/coordination
- Cannot be scaled up to any size
- Expensive to build one big system
- Programming with **OpenMP**

Distributed memory systems (again!)



- Processor only sees own memory
- Performance of the network is key
- Programming with **Message Passing**

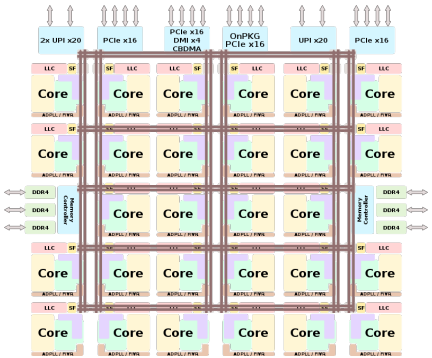
Multicore CPU: Xeon Platinum 8280M Cascade Lake-SP

Performance

- FLOPs: 32 · frequency · cores
  - 28 cores, 2.7 GHz (1.8 GHz AVX512)
  - ⇒ 2.2 TFLOPs
- 6 Channel DDR4, max 2.933 GHz
  - Throughput 131 GB/s
- Power: 205 Watt

Architecture

- Each core executes code independently
  - Feature rich: speculative execution, ...
- Each core has two AVX-512 units
  - Vector parallelism on 512 bits



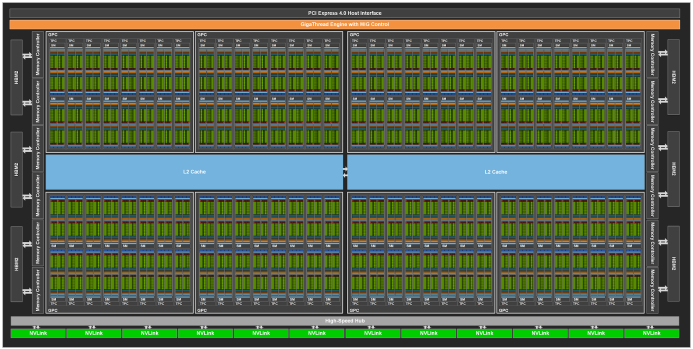
- Summary: complex architecture, heavy cores, optimized for latency

Manycore GPU: NVIDIA A100

Accelerated computing is outside of this course, but concepts are transferrable

Performance

- FLOPs: 9.7 TFLOPs FP64
  - 312 TFLOPs Tensor (FP16)
  - 1.41 GHz
- 40 GByte HBM2 memory
  - 10 memory channels
  - Throughput 1600 GB/sec
- Power: 400 Watt



Architecture

- 128 Streaming multiprocessors
  - Each with 32 FP64 cores

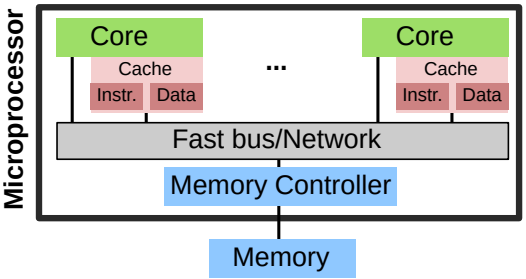
  ⇒ 4096 cores per GPU

- Summary: Simple cores, optimized for throughput
- Problem: deep pipeline, higher latency, costly startup time of program

Parallel Programs

- A **parallel program** runs on parallel hardware
  In the strict sense: A parallel application coordinates concurrent processing

Schema of a multicore processor



Processor provides all parallelism levels

- Multiple ALU/other units
- Pipelining of processing stages
- SIMD: Single Instruction - Multiple Data
  - Same operation on multiple data
  - Instruction set: SSE, AVX
- Multiple cores
  - Each with own instruction pointer
- May use (GPU) accelerators
  - CPU in charge of processing

https://en.wikipedia.org/wiki/Microarchitecture

Group Work

- Think about an application of parallel computation
  - Describe the use case briefly
- What computation is performed in parallel?
- Which architecture / hardware presented would you like to use for it?
- Time: 5 min
- Organization: breakout groups - please use your mic or chat

Challenges

- Programming: imports errors from distributed computed +
  - Low-level APIs and code-optimization to achieve performance
  - Performance-optimized code is difficult to maintain
  - Expensive and challenging to debug 1'000 concurrently running processes
  - Utilizing all compute resources efficiently (load balancing)
  - Grand challenges are difficult to test, as nobody knows the true answer
- Performance engineering: Optimizing code is main agenda for HPC
  - Covered in this course
- Scalability: stricter than distributed systems
  - Strong-scaling: same problem, more parallelism shall improve performance
  - Weak-scaling: data scales with processors, retain time-to-solution
- Environment: bleeding edge and varying hardware/software systems
  - Special-purpose hardware (FPGA/ASIC Application-Specific Integrated Circuit)
  - Limited knowledge to administrate, use, and to compare performance

Outline

Programming

- Let's investigate how to create a "parallel" program

Abstractions and examples

- Sequential code to compute vector addition
- Automatically parallelizable code for shared memory using OpenMP
  - Parallelizes code based on user-provided directives
- Manual parallelization for distributed memory using Message passing

Vector Addition: Sequential CPU Code

Compute function

```
1  void vecAdd(int * restrict a, int * restrict b, int * restrict c, int n){
2          for(int i=0; i < n; i++){
3                  c[i] = a[i] + b[i];
4          }
5  }
```

Execution

```
1  int a[8];
2  int b[8];
3  int c[8];
4  // fill a and b somehow
5  vecAdd(a, b, c, 8);
```

- Both codes may be placed in the same file $\Rightarrow$ we call this a "single source"

Directive-Based Parallelism using OpenMP: CPU Code

Compute function

```
1  void vecAdd(int * restrict a, int * restrict b, int * restrict c, int n){
2          //Preprocessor directive telling compiler to parallelize for loops
3          #pragma OMP parallel for
4          for(int i=0; i < n; i++){
5                  c[i] = a[i] + b[i];
6          }
7  }
```

- The same code as before, just compile with -fopenmp...

Execution

```
1  int a[8];
2  int b[8];
3  int c[8];
4  // fill a and b with values ...
5  vecAdd(a, b, c, 8);
```

Message Passing

Definition

- Message passing is the sending of a message to a process[4]
- What: any data from the memory of the sender
- How: Programmer explicitly requests send/recv

Content of a message

- Header (Sender, receiver, type[5])
- Data (from memory)

Addressing

- How to define to whom I sent, from whom to receive?
  - Addressing via "process number": Rank 0 - (N-1)
  - Processes are enumerated upon start

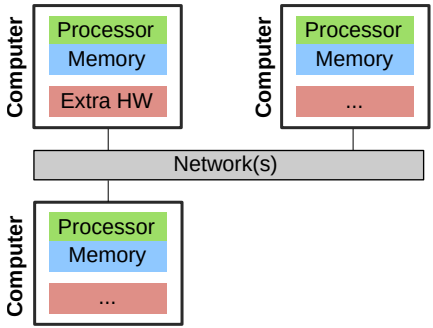
[4] The general definition in distributed systems is more generic

[5] Distinguishs different messages

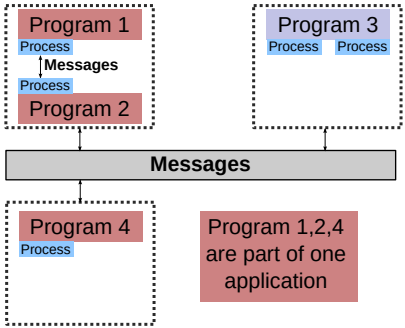
Example Execution of an Message Processing Program

- Processes are instances of an application
  - Executed on different computers
  - May execute the same or different code
  - Addressing via enumeration of the processes
- Different applications can be executed concurrently

Hardware perspective



Software perspective



Programming with Message Passing

- Code of processes of the program define how they cooperate
- Important standard: The Message Passing Interface (MPI)
  - MPI implementations are a library with communication functions

Single Program Multiple Data (SPMD)

- SPMD: A single binary program created from one source code
- Every process of a program runs on different data

Example message passing

```
1  int Rank = getRank(); // Determine my rank
2  if(Rank == 0){
3          // Send message (18 bytes to Rank 1)
4          send(1, 18, "Hello from rank 0");
5  }else if(Rank == 1){
6          char data[100];
7          // Receive message from Rank 0
8          receive(0, 18, data);
9          printf("%s\n", data);
10 }
```

Concurrent Execution

- Assumption: our example program is executed with two processes
  - Instructions of both processes are executed concurrently and independently

Executed code

Prozess 0

```
int rang = getRank();  // returns 0
if(rang == 0){
  send(1, 18, "Hello from rank 0");
}else...

}
```

Message

Prozess 1

```
int rang = getRank();  // returns 1
if(rang == 0){

}else if(rang == 1){
  char data[100];
  receive(0, 18, data);
  printf("%s\n", data);
}
```

- Semantics of message exchange is defined by operation/function
  - Receive must block until a suitable message is received
  - Sending might complete before message is actually received/processed
- Program code is **parallelizable** if any paralell and concurrent execution path leads to the **same solution**

Outline

Computational Science

- Talking about computer-aided simulation, we mean computational science

Definitions

- Multidisciplinary field using advanced computing capabilities to understand and solve complex problems
  - Typically using mathematical models and computer simulation
  - Problems are motivated by industrial or societal challenges
- May utilize single computer, distributed systems, or supercomputers

Examples utilizing distributed computing

- Finding the higgs boson (CERN)
- Bioinformatics applications, e.g., gene sequencing

Examples utilizing high-performance computing

- Computing the weather forecast for tomorrow / next week
- Simulating a tokamak fusion reactor

https://en.wikipedia.org/wiki/Computational_science

Summary

- HPC and supercomputers are enablers for scientific computing
- Supercomputers are relevant for data science
- Parallel computing is the simultaneous calculation/execution
- Shared-memory, distributed-memory and GPU-Architectures differ
- GPUs are accelerating CPUs for massively parallel workloads
- Programming can be challenging
- Programming paradigms
  - Auto-parallelization with compiler-directives (OpenMP, shared mem)
  - Parallelization with Message Passing (distributed computing)
- Simple example: Vector addition
